

Analysis of Vaccinated versus Unvaccinated populations in Israel, since the beginning of the Vaccination Program.

J. Steen MBA, 30 August 2021

Abstract

Israel is one of the most vaccinated countries in the world and is publishing health data about the Covid-19 pandemic. Analysis of this real-life data reveals another story than what generally is being portraited, based on modelling predictions. The world is not as bad, and the vaccines are not as good.

There is no merit in vaccinating all age groups and vaccine mandates are inconsistent with the ability of the vaccine to reduce the spread. A targeted approach aimed at the elderly age groups is sufficient to tackle the drawbacks of the pandemic.

Especially when vaccines are in short supply it is better to vaccinate the elderly with booster shots than vaccinating all age groups.

With the emergence of the Delta variant, risks of serious adverse effects is greater than the Crude Mortality Ratio of their age group for most of the population.

Background

The Australian government has embarked on a roadmap out of lockdowns via mass vaccination based on modelling from the Doherty Institute. Why is this plan based on modelling whilst there is real-life data available from other countries that have encountered severe outbreaks of Covid-19 and that are ahead in the vaccination-drive?

Israel started immunising their population on 20th Dec 2020 and reached an immunisation rate of 63.4% on 21st August 2021 with an immunisation rate in all age groups above 19 of more than 80%. In this period Israel experienced a major outbreak of Covid-19 (Alpha variant) and at the end of this period an outbreak of the Delta variant is emerging whilst having very high vaccination rates in the most vulnerable age groups.

This study analyses publicly available data from Israel and derives epidemiological and immunological parameters from this data and investigates the differences in the Alpha and Delta variant outbreaks.

Method

The data is derived from publicly available data from the Israeli Governmentⁱ and Health Departmentⁱⁱ. The Daily Vaccination data, Cases and Events amongst Vaccinated are combined into one spreadsheet to be able to compare vaccination data with epidemiological data. The spreadsheet can provide aggregate data for each age group and

determines the unvaccinated and vaccinated populations based on the average vaccination rate of the selected period. This provides data for the vaccinated population versus the unvaccinated control group.

The data is analysed for the whole period, the Alpha outbreak and the developing Delta outbreak. For visualisation of the outbreak periods and vaccination drive see Appendix 1 and 2.

The Alpha outbreak period is taken from the beginning of vaccinations until end march when the Alpha outbreak was nearly petered out and when the daily vaccinations started to drop (due to high vaccination rates) It covers a complete period from build-up, peak and petering out (daily deaths ±15 to 76 and back down to ± 10).

The Delta outbreak looks at the period of beginning July until end of available data. Interesting to note is that at the end 1.4 million booster doses had been administered to the elderly age groups.

To make the appropriate conclusions about the data, benchmarks are set for the Crude Mortality Ratio (CMR), the Relative Risk Ratio (RRR) and the Number Needing Treatment (NNT).

The only adjustment to the downloaded data is to change '<5' notations for the weekly reported cases amongst vaccinated to 1.2 to enable aggregation calculations.

Results

Crude Mortality Rates

Based on 'whole period' sample of 604,821 cases the CMR for the Unvaccinated population = 0.038%. If projected to the Australian population this would equate to approximately 9500 deaths if no vaccination would take place. Looking at the Delta variant the CMR is 0.003% and excluding the 0-19 years old age group it is 0.015%. This would translate to approximately 3.3 thousand deaths for the whole Australian population if unvaccinated. This is comparable to normal Influenza mortality rates. (See appendix 6).

For any period, the Vaccination risk is higher than the CMR of the Unvaccinated for all ages below 40 years old.

For the Delta variant, as the Case Fatality Ratios (CFR) are significantly lower than the Alpha variant in all Age groups, the Vaccination Risk is higher than the CMR for the Unvaccinated below 60 years old.

Relative Risk Reduction

The RRR (often referred to as efficacy) is very low (even sometimes negative) for infections (positive cases). This confirms the suspicion that the vaccines do not stop the spread.

The RRR for avoiding Hospitalisation is approximately 70% for the age group 40-49 and lowers with the older age groups.

The RRR in avoiding deaths is approximately 56% for the age group 70-79 and drops in the higher age groups. The NNT (Death) for Ages below 70 is very high because the Absolute Risk (AR) for these age groups is very low in the first place.

The RRR's for Age groups above 70 seem to benefit from the booster shots (at this stage).

Discussion

RRR versus Absolute Risk Reduction (ARR) discussion.

There is debate amongst scientists about the Vaccine Trial results and the use of RRR as a representation of efficacy. Many claim the use of RRR is misleading. This is all dependant on the rate of infection. This can be demonstrated with this collection of data. Consider the analysis result for the period of 2-5-21 until 20-6-21. (Appendix 7). In this period (in between Alpha and Delta outbreaks) the infection rate is very low and the average daily deaths is below 1. The RRR's are looking pretty descent, but the NNT's are very high because the risk of infection is very low in this period. (CMR for this period = 0.001% or 10 in a million)

Thus, RRR is not always a good indication for efficacy as base of the ratio can be very thin and not statistically solid. For this reason, a benchmark NNT of 1000 is used.

It raises the question if the epidemiological strain on the population that was used for the vaccine trials, was appropriate.

Vaccination Risk

See Appendix 8 for an overview of adverse events after vaccination as reported by the TGA. Whilst the TGA only recognises 7 deaths due to vaccinations it is very likely that there is underreporting of all events. The reported events about Myocarditis and Pericarditis indicate a risk of 0.006% by itself. It is very likely that the total risk of vaccination is higher than 0.006%, which is used as benchmark in this analysis.

Booster Shots

Since the beginning of August 'booster shots' (dose 3) have been administered to the older age groups. It seems that these booster shots help in avoiding cases in these elderly groups. If the last week of the dataset is taken out of the analysis the RRR's for Cases amongst these age groups drop, but the NNT's also increase as it shifts to only the beginning of the outbreak.

Another question is if the habits of the age groups influence the outcomes. The older the less likely are people to mingle with a lot of other people. If you compare the Age Group 60-69 with 58% Booster shot ratio to the Age Group 70-79 with a 74% Booster shot ratio the RRR's are halved.

How exactly the parameters of the booster shots will develop over time and how long the effect will last remains to be seen.

Conclusion

- Vaccinations do **not** significantly reduce the spread.
 - The Real-life Efficacy of the vaccine is lower than the often publicly quoted 90 to 95%.
 - The Vaccination Risk is higher than the CMR for all ages below 40.
(The benchmark used for Vaccination Risk is likely to be low)
 - There is merit to vaccinations to avoid Hospitalisation for the age groups 40 – 59 and some merit for the age groups 60-79 for the Alpha variant.
For the Delta variant there is some merit to avoid Hospitalisation for the age groups above 70.
 - There is some merit to vaccinations to avoid Death for the age groups above 70.
-
- There is no merit in vaccinating all age groups and vaccination mandates are inconsistent with the ability of the vaccine to reduce the spread.
 - A targeted vaccination program to age groups above 60 (with booster shots) is more productive than vaccinating all age groups. (Especially in a situation with short supply.)
